

# Introduction to Python

## **Direct Loops: For Loops**

# Topics

## I) For Loops

# For Loops

In general, a loop allows a sequence of instructions to execute some task repeatedly until some condition is met.

Python's *for* loop iterates over items of a sequence (e.g. a list, string or tuple) and process them with some code.

```
for x in sequence:  
    block
```

This is a list. More on lists in a later lecture.

```
for x in [2,3,5,7]:  
    print(x, end=" ")
```

*# print all on same line*

2 3 5 7

# For Each Loops

```
for x in [2,3,5,7]:  
    print(x)
```

2

3

5

7

```
for x in "hello":  
    print(x)
```

h

e

l

l

o

Iterate through each number in the list.

"for each x in" list.

Iterate through each character in the string.

# range(stop)

A simple use of a *for* loop runs some code a specified number of times using the *range()* function.

`range(stop)`: returns sequence of numbers from 0 (default) up to but not including stop. Increment by 1 (default).

```
for i in range(10):  
    print(i, end=" ")
```

0 1 2 3 4 5 6 7 8 9

# range(start, stop)

range(start, stop): from start up to but not including stop. Increment by 1 (default).

```
for i in range(2, 8):  
    print(i, end=' ')
```

2 3 4 5 6 7

# range(start, stop, step)

range(start, stop, step): from start up to but not including stop, increment by step.

```
for i in range(1, 10, 2):  
    print(i, end=' ')
```

1 3 5 7 9

If step is negative, a list can be traversed backwards.

```
for i in range(10, 2, -1):  
    print(i, end=' ')
```

10 9 8 7 6 5 4 3

# Definite Loop

The for loop is an example of a **definite** loop. We can determine ahead of time the number of times the loop repeats. Later, we will talk about **indefinite loop**, a loop where we cannot predict the number of times a loop repeats.

```
for i in range(5):  
    print("*", end="")  
  
*****
```

The loop above prints five '\*'s. We can determine this ahead of time from the for loop statement.

# Summing and Counting

There are two common tasks that uses for loops.

- 1) Summing
- 2) Counting

# Summing Values

Write a segment of code that solve the problem

$$1 + 2 + 3 + \dots + 98 + 99 + 100.$$

We need a variable that accumulate the sum at each iteration of the loop. This variable should be initialized to 0.

```
sum = 0
for i in range(1, 101):
    sum += i
```

# Writing a function to sum

Now write a function that accepts a non-negative integer input  $n$  and returns the sum of integers from 1 to  $n$ (including).

```
def sum(n):  
    sum = 0  
    for i in range(1, n+1):  
        sum += i  
    return sum
```

```
print(sum(5))    # 1+2+3+4+5=15
```

```
a = sum(100)     # a = 5050
```

```
print(a)         # 5050 is printed on console
```

# Conditional Summing

Write a segment of code that compute the sum of all numbers from 1 to 100 that are multiples of 3.

```
sum = 0
for i in range(0, 101, 3):
    sum += i
```

Or equivalently, we can use a conditional to select the numbers to add:

```
sum = 0
for i in range(1, 101):
    if i % 3 == 0:
        sum += i
```

Better to use if conditional for filtering.  
In general, using the step size above  
might not always work.

# Conditional Summing Example

Write a segment of code that compute the sum of all numbers from 1 to 100.  
However:

- 1) if a number is a multiple of 3, double it before adding,
- 2) if a number is a multiple of 5, triple it before adding,
- 3) If a number is a multiple of both, quadruple it before adding.
- 4) otherwise, just add the number.

# Conditional Summing Solution?

Is the following a correct solution?

```
sum = 0
for i in range(1, 101):
    if i % 3 == 0:
        sum += 2 * i
    elif i % 5 == 0:
        sum += 3 * i
    elif i % 3 == 0 and i % 5 == 0:
        sum += 4 * i
    else:
        sum += i
```

No! Why not?

# Conditional Summing Solution

The following is correct.

```
sum = 0
for i in range(1, 101):
    if i % 3 == 0 and i % 5 == 0:
        sum += 4 * i
    elif i % 3 == 0:
        sum += 2 * i
    elif i % 5 == 0 :
        sum += 3 * i
    else:
        sum += i
```

# Counting

Write a function that accepts an integer  $n$  and returns the number of factors of  $n$ .

```
def count_factors(n):  
    count = 0  
    for i in range(1, n+1):  
        if n % i == 0:          # i is a factor of n  
            count += 1  
    return count
```

```
print(count_factors(10))  # 4 (factors of 10 = {1,2,5,10})  
print(count_factors(7))  # 2 (factors of 7 = {1,7})
```

# For Loop in Movies and TV-Shows

## **Movies:**

Groundhog Day(1993); Bill Murray.

Looper(2010); Bruce Willis and Joseph Gordon-Levitt, Emily Blunt.

Edge of Tomorrow(2014); Tom Cruise, Emily Blunt.

Happy Death Day(2017).

## **TV-Show:**

Russian Doll(Netflix, Emmy-Nominated)

# Lab I

Create a new repl on [repl.it](https://repl.it).

Write a **for loop** to do each of the following:

- 1) Print out "Hello!" 10 times, each on a different line.
- 2) Alternate between printing "Hello" and "Hi" for a total of 20 times, each on a separate line. Use only one for loop. (Hint: Use a conditional)
- 3) Print 1 4 9 16 25 ... 100
- 4) Print 10 8 6 4 2 0 -2
- 5) Compute the sum:  $1^2 + 2^2 + 3^2 + 4^2 + \dots + 19^2 + 20^2$

# Lab 2: Counting Primes

Create a new repl.

1) Rewrite the function `count_factors` as explained in a previous slide.

2) A number  $n$  is prime if its only factors are 1 and  $n$ . Write the function `is_prime` which accepts an integer  $n$  and returns whether it is prime. Note that 1 is not prime. **You must call the function `count_factors` in your implementation of `is_prime`.**

`is_prime(13)` returns `True`

`is_prime(1245)` returns `False`

3) Write the function `num_primes` which accepts an integer  $n$  and returns the number of primes up to and including  $n$ . **You must call the function `is_prime` in your implementation.**

`num_prime(11)` returns 5 since 2, 3, 5, 7, 11 are the 5 prime numbers less than or equal to 11.

Call the three above functions with different inputs and make sure that your functions work as expected.
