

CSP Exam Reference Sheet

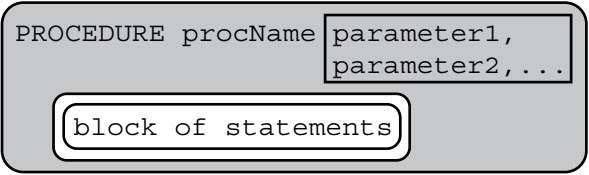

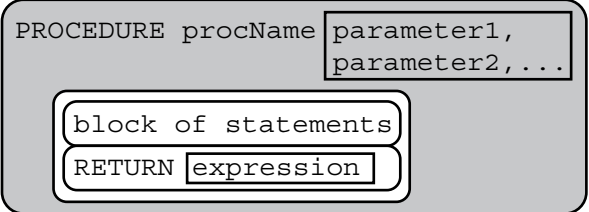

RED BLOCK OF TEXT ARE ADDED TO THIS DOCUMENT TO DIFFERENTIATE BETWEEN THIS SYNTAX AND PYTHON'S.

Instruction	Explanation
Assignment, Display, and Input	
Text: <code>a ← expression</code> Block: 	Evaluates <code>expression</code> and then assigns a copy of the result to the variable <code>a</code> .
Text: <code>DISPLAY(expression)</code> Block: 	Displays the value of <code>expression</code> , followed by a space.
Text: <code>INPUT()</code> Block: <code>INPUT</code>	Accepts a value from the user and returns the input value.
Arithmetic Operators and Numeric Procedures	
Text and Block: <code>a + b</code> <code>a - b</code> <code>a * b</code> <code>a / b</code>	The arithmetic operators <code>+</code> , <code>-</code> , <code>*</code> , and <code>/</code> are used to perform arithmetic on <code>a</code> and <code>b</code> . For example, <code>17 / 5</code> evaluates to <code>3.4</code> . The order of operations used in mathematics applies when evaluating expressions.
Text and Block: <code>a MOD b</code>	Evaluates to the remainder when <code>a</code> is divided by <code>b</code> . Assume that <code>a</code> is an integer greater than or equal to <code>0</code> and <code>b</code> is an integer greater than <code>0</code> . For example, <code>17 MOD 5</code> evaluates to <code>2</code> . The <code>MOD</code> operator has the same precedence as the <code>*</code> and <code>/</code> operators.
Text: <code>RANDOM(a, b)</code> Block: <code>RANDOM</code> 	Generates and returns a random integer from <code>a</code> to <code>b</code> , including <code>a</code> and <code>b</code> . Each result is equally likely to occur. For example, <code>RANDOM(1, 3)</code> could return <code>1</code> , <code>2</code> , or <code>3</code> .
Relational and Boolean Operators	
Text and Block: <code>a = b</code> <code>a ≠ b</code> <code>a > b</code> <code>a < b</code> <code>a ≥ b</code> <code>a ≤ b</code>	The relational operators <code>=</code> , <code>≠</code> , <code>></code> , <code><</code> , <code>≥</code> , and <code>≤</code> are used to test the relationship between two variables, expressions, or values. A comparison using relational operators evaluates to a Boolean value. For example, <code>a = b</code> evaluates to <code>true</code> if <code>a</code> and <code>b</code> are equal; otherwise it evaluates to <code>false</code> .

Instruction	Explanation
Relational and Boolean Operators (continued)	
Text: NOT condition Block: NOT (condition)	Evaluates to true if condition is false; otherwise evaluates to false.
Text: condition1 AND condition2 Block: (condition1) AND (condition2)	Evaluates to true if both condition1 and condition2 are true; otherwise evaluates to false.
Text: condition1 OR condition2 Block: (condition1) OR (condition2)	Evaluates to true if condition1 is true or if condition2 is true or if both condition1 and condition2 are true; otherwise evaluates to false.
Selection	
Text: IF(condition) { <block of statements> } Block: 	The code in block of statements is executed if the Boolean expression condition evaluates to true; no action is taken if condition evaluates to false.
Text: IF(condition) { <first block of statements> } ELSE { <second block of statements> } Block: 	The code in first block of statements is executed if the Boolean expression condition evaluates to true; otherwise the code in second block of statements is executed.

Instruction	Explanation
Iteration	
Text: REPEAT n TIMES { <block of statements> } Block: 	The code in <code>block of statements</code> is executed <code>n</code> times.
Text: REPEAT UNTIL(condition) { <block of statements> } Block: 	The code in <code>block of statements</code> is repeated until the Boolean expression <code>condition</code> evaluates to <code>true</code> . This is different than Python's while loop. Python's while loop runs as long as the condition is true and terminates when the condition is false. REPEAT UNTIL (condition) loop runs as long as the condition is false and terminates when the condition is true.
List Operations	
For all list operations, if a list index is less than 1 or greater than the length of the list, an error message is produced and the program terminates.	
Text: <code>aList ← [value1, value2, value3, ...]</code> Block: 	Creates a new list that contains the values <code>value1</code> , <code>value2</code> , <code>value3</code> , and <code>...</code> at indices 1, 2, 3, and <code>...</code> respectively and assigns it to <code>aList</code> .
Text: <code>aList ← []</code> Block: 	Creates an empty list and assigns it to <code>aList</code> .
Text: <code>aList ← bList</code> Block: 	Assigns a copy of the list <code>bList</code> to the list <code>aList</code> . For example, if <code>bList</code> contains <code>[20, 40, 60]</code> , then <code>aList</code> will also contain <code>[20, 40, 60]</code> after the assignment.
Text: <code>aList[i]</code> Block: <code>aList</code> 	Accesses the element of <code>aList</code> at index <code>i</code> . The first element of <code>aList</code> is at index 1 and is accessed using the notation <code>aList[1]</code> . Python's list index starts at 0. Here, list starts at index 1.

Instruction	Explanation
List Operations (continued)	
Text: <code>x ← aList[i]</code> Block: 	Assigns the value of <code>aList[i]</code> to the variable <code>x</code> .
Text: <code>aList[i] ← x</code> Block: 	Assigns the value of <code>x</code> to <code>aList[i]</code> .
Text: <code>aList[i] ← aList[j]</code> Block: 	Assigns the value of <code>aList[j]</code> to <code>aList[i]</code> .
Text: <code>INSERT(aList, i, value)</code> Block: 	Any values in <code>aList</code> at indices greater than or equal to <code>i</code> are shifted one position to the right. The length of the list is increased by 1, and <code>value</code> is placed at index <code>i</code> in <code>aList</code> .
Text: <code>APPEND(aList, value)</code> Block: 	The length of <code>aList</code> is increased by 1, and <code>value</code> is placed at the end of <code>aList</code> .
Text: <code>REMOVE(aList, i)</code> Block: 	Removes the item at index <code>i</code> in <code>aList</code> and shifts to the left any values at indices greater than <code>i</code> . The length of <code>aList</code> is decreased by 1.
Text: <code>LENGTH(aList)</code> Block: 	Evaluates to the number of elements in <code>aList</code> .
Text: <code>FOR EACH item IN aList</code> <code>{</code> <code> <block of statements></code> <code>}</code> Block: 	The variable <code>item</code> is assigned the value of each element of <code>aList</code> sequentially, in order, from the first element to the last element. The code in <code>block of statements</code> is executed once for each assignment of <code>item</code> .

Instruction	Explanation
Procedures and Procedure Calls	
<p>Text:</p> <pre>PROCEDURE procName(parameter1, parameter2, ...)</pre> <pre>{ <block of statements> }</pre> <p>Block:</p> 	<p>Defines <code>procName</code> as a procedure that takes zero or more arguments. The procedure contains <code>block of statements</code>.</p> <p>The procedure <code>procName</code> can be called using the following notation, where <code>arg1</code> is assigned to <code>parameter1</code>, <code>arg2</code> is assigned to <code>parameter2</code>, etc:</p> <pre>procName(arg1, arg2, ...)</pre> <p>Equivalent to Python's function:</p> <pre>def procName(parameter1, parameter2,...): block of statements</pre>
<p>Text:</p> <pre>PROCEDURE procName(parameter1, parameter2, ...)</pre> <pre>{ <block of statements> RETURN(expression) }</pre> <p>Block:</p> 	<p>Defines <code>procName</code> as a procedure that takes zero or more arguments. The procedure contains <code>block of statements</code> and returns the value of <code>expression</code>. The <code>RETURN</code> statement may appear at any point inside the procedure and causes an immediate return from the procedure back to the calling statement.</p> <p>The value returned by the procedure <code>procName</code> can be assigned to the variable <code>result</code> using the following notation:</p> <pre>result ← procName(arg1, arg2, ...)</pre>
<p>Text:</p> <pre>RETURN(expression)</pre> <p>Block:</p> 	<p>Returns the flow of control to the point where the procedure was called and returns the value of <code>expression</code>.</p>
Robot	
<p>If the robot attempts to move to a square that is not open or is beyond the edge of the grid, the robot will stay in its current location and the program will terminate.</p>	
<p>Text:</p> <pre>MOVE_FORWARD ()</pre> <p>Block:</p> 	<p>The robot moves one square forward in the direction it is facing.</p>
<p>Text:</p> <pre>ROTATE_LEFT ()</pre> <p>Block:</p> 	<p>The robot rotates in place 90 degrees counterclockwise (i.e., makes an in-place left turn).</p>

Instruction	Explanation
Robot	
Text: ROTATE_RIGHT() Block: <div data-bbox="131 317 355 369" style="border: 1px solid black; border-radius: 10px; padding: 2px 10px; display: inline-block;">ROTATE_RIGHT</div>	The robot rotates in place 90 degrees clockwise (i.e., makes an in-place right turn).
Text: CAN_MOVE(direction) Block: CAN_MOVE <div data-bbox="277 495 448 537" style="border: 1px solid black; padding: 2px 10px; display: inline-block;">direction</div>	Evaluates to <code>true</code> if there is an open square one square in the direction relative to where the robot is facing; otherwise evaluates to <code>false</code> . The value of <code>direction</code> can be <code>left</code> , <code>right</code> , <code>forward</code> , or <code>backward</code> .
