

Unit 3: Boolean Expressions, if statements if-else if-else statements

Adapted from:

- 1) Building Java Programs: A Back to Basics Approach
by Stuart Reges and Marty Stepp
- 2) Runestone CSAwesome Curriculum

Type boolean

- **boolean**: A logical type whose values are `true` and `false`.
 - It is legal to:
 - create a `boolean` variable
 - pass a `boolean` value as a parameter
 - return a `boolean` value from methods
 - call a method that returns a `boolean` and use it as a test

```
int age = 22;  
boolean minor      = (age < 21); // false  
boolean lovesAPCS = true;  
boolean is1049Prime = isPrime(1049);
```

Using boolean

- Why is type `boolean` useful?
 - Can capture a complex logical test result and use it later
 - Can write a method that does a complex test and returns it
 - Makes code more readable
 - Can pass around the result of a logical test (as param/return)

```
int age = 21, height = 88;  
double salary = 100000;
```

```
boolean goodAge      = age >= 12 && age < 29; //true  
boolean goodHeight   = height >= 78 && height < 84; //false  
boolean rich         = salary >= 100000.0; //true
```

NOTE: && is the "and" operator. See slide 13.

Relational expressions

- Tests use *relational operators*:

Operator	Meaning	Example	Value
==	equals	1 + 1 == 2	true
!=	does not equal	3.2 != 2.5	true
<	less than	10 < 5	false
>	greater than	10 > 5	true
<=	less than or equal to	126 <= 100	false
>=	greater than or equal to	5.0 >= 5.0	true

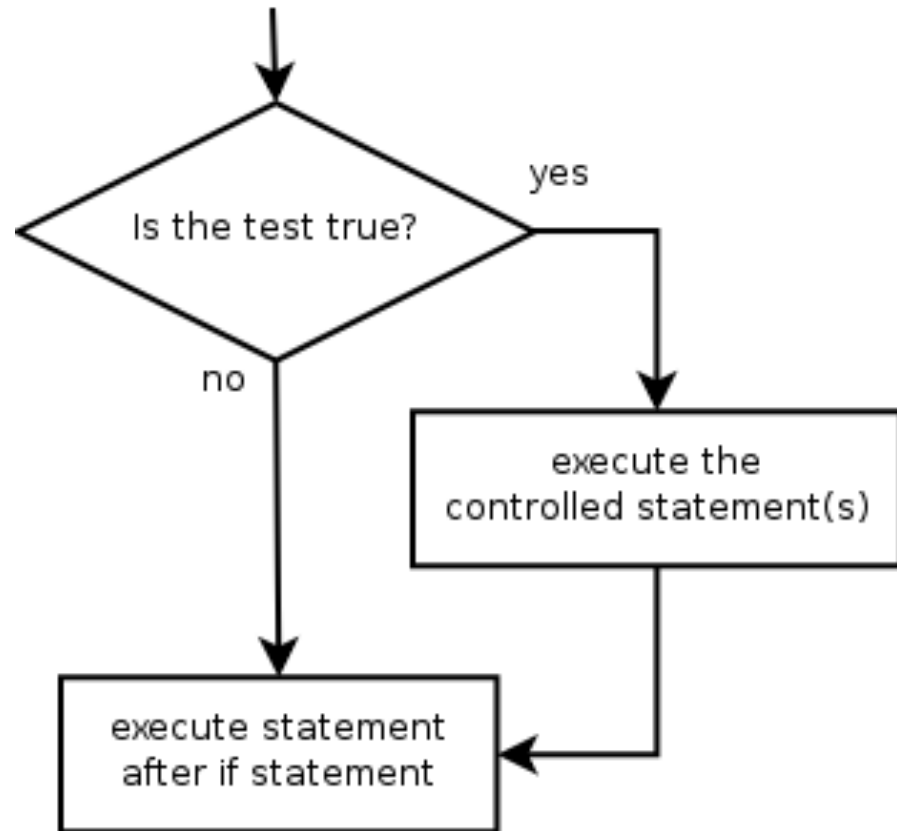

Relational Expressions

```
public class Boolean_Class{  
    public static void main(String[] args){  
        int x = 2, y = 3;  
        System.out.println(x == y); // false  
        System.out.println(x != y); // true  
        System.out.println(2 + 4 * 3 <= 15); // true  
        System.out.println(x > 5); // false  
        System.out.println(y >= 3); // true  
    }  
}
```

The `if` statement

Executes a block of statements only if a test is true

```
if (test) {  
    statement;  
    ...  
    statement;  
}  
statement;
```

The `if` statement

```
double gpa = 2.1;  
if (gpa >= 2.0) {  
    System.out.println("Application accepted.");  
}
```

Output:

Application accepted.

```
double gpa = 1.9;  
if (gpa >= 2.0) {  
    System.out.println("Application accepted.");  
}
```

Output: (No output)

The if/else statement

Executes one block if a test is true, another if false

```
if (test) {  
    statement(s);  
} else {  
    statement(s);  
}
```

- **Example:**

```
double gpa = console.nextDouble();  
if (gpa >= 2.0) {  
    System.out.println("Welcome to Mars University!");  
} else {  
    System.out.println("Application denied.");  
}
```

The if/else statement

```
double gpa = 3.0;  
if (gpa >= 2.0){  
    System.out.println("Welcome to Mars University!");  
}  
else{  
    System.out.println("Application denied.");  
}
```

Output:

Welcome to Mars University.

The if/else statement

```
double gpa = 1.0;  
if (gpa >= 2.0){  
    System.out.println("Welcome to Mars University!");  
}  
else{  
    System.out.println("Application denied.");  
}
```

Output:

Application denied.

Misuse of if

- What's wrong with the following code?

```
int percent = <Code to ask user to enter a percentage>
```

```
if (percent >= 90) {  
    System.out.println("You got an A!");  
}  
if (percent >= 80) {  
    System.out.println("You got a B!");  
}  
if (percent >= 70) {  
    System.out.println("You got a C!");  
}  
if (percent >= 60) {  
    System.out.println("You got a D!");  
}  
if (percent < 60) {  
    System.out.println("You got an F!");  
}  
...
```

Misuse of if

- What's wrong with the following code?

```
int percent = 90;

if (percent >= 90) {
    System.out.println("You got an A!");
}
if (percent >= 80) {
    System.out.println("You got a B!");
}
if (percent >= 70) {
    System.out.println("You got a C!");
}
if (percent >= 60) {
    System.out.println("You got a D!");
}
if (percent < 60) {
    System.out.println("You got an F!");
}
...
```

Output:
You got an A!
You got a B!
You got a C!
You got a D!
You got an F!

Nested if/else

Chooses between outcomes using many tests

```
if (test) {  
    statement(s);  
} else if (test) {  
    statement(s);  
} else {  
    statement(s);  
}
```

- **Example:**

```
if (x > 0) {  
    System.out.println("Positive");  
} else if (x < 0) {  
    System.out.println("Negative");  
} else {  
    System.out.println("Zero");  
}
```

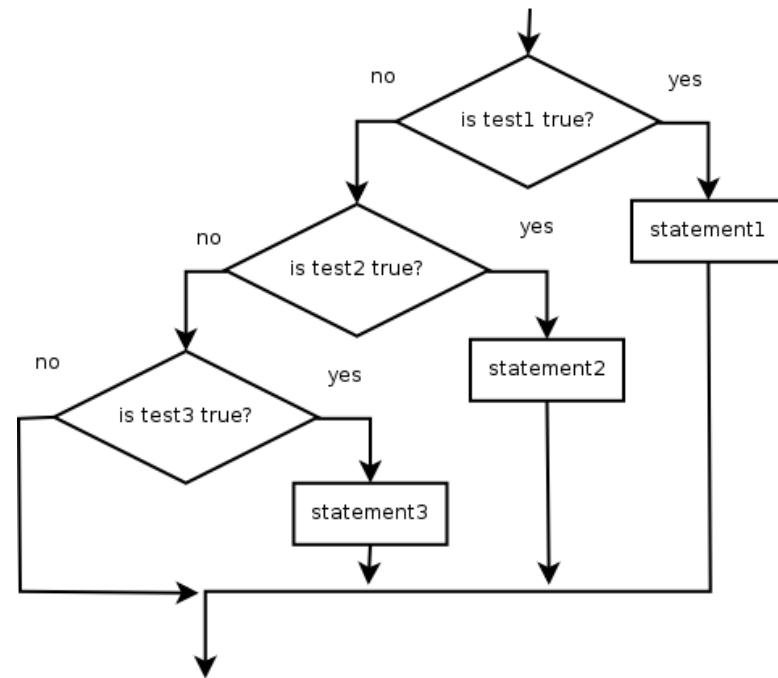

Nested if/else/if

- If it ends with `else`, exactly one path must be taken.
- If it ends with `if`, the code might not execute any path.

```
if (test) {  
    statement(s);  
} else if (test) {  
    statement(s);  
} else if (test) {  
    statement(s);  
}
```

- Example:

```
if (place == 1) {  
    System.out.println("Gold medal!");  
} else if (place == 2) {  
    System.out.println("Silver medal!");  
} else if (place == 3) {  
    System.out.println("Bronze medal.");  
}
```

Nested if structures

- exactly 1 path (*mutually exclusive*)

```
if (test) {  
    statement(s);  
} else if (test) {  
    statement(s);  
} else {  
    statement(s);  
}
```

- 0 or 1 path (*mutually exclusive*)

```
if (test) {  
    statement(s);  
} else if (test) {  
    statement(s);  
} else if (test) {  
    statement(s);  
}
```

- 0, 1, or many paths (*independent tests; not exclusive*)

```
if (test) {  
    statement(s);  
}  
if (test) {  
    statement(s);  
}  
if (test) {  
    statement(s);  
}
```

Which nested if/else?

- **(1) if/if/if (2) nested if/else (3) nested if/else/if**
 - Whether a user is lower, middle, or upper-class based on income.
 - **(2)** nested `if / else if / else`
 - Whether you made the dean's list ($\text{GPA} \geq 3.8$) or honor roll (3.5-3.8).
 - **(3)** nested `if / else if`
 - Whether a number is divisible by 2, 3, and/or 5.
 - **(1)** sequential `if / if / if`
 - Computing a grade of A, B, C, D, or F based on a percentage.
 - **(2)** nested `if / else if / else if / else if / else`

"Boolean Zen", part 1

- Students new to `boolean` often test if a result is `true`:

```
if (isPrime(57) == true) {      // bad
    ...
}
```

- But this is unnecessary and redundant. Preferred:

```
if (isPrime(57)) {             // good
    ...
}
```

- A similar pattern can be used for a `false` test:

```
if (isPrime(57) == false) {    // bad
if (!isPrime(57)) {            // good
```

"Boolean Zen", part 2

- Methods that return `boolean` often have an `if/else` that returns `true` or `false`:

```
public static boolean bothOdd(int n1, int n2) {  
    if (n1 % 2 != 0 && n2 % 2 != 0) {  
        return true;  
    } else {  
        return false;  
    }  
}
```

- But the code above is unnecessarily verbose.

"Boolean Zen", part 3

- We could store the result of the logical test.

```
public static boolean bothOdd(int n1, int n2) {  
    boolean test = (n1 % 2 != 0 && n2 % 2 != 0);  
    if (test) {    // test == true  
        return true;  
    } else {      // test == false  
        return false;  
    }  
}
```

- Notice: Whatever `test` is, we want to return that.
 - If `test` is `true` , we want to return `true`.
 - If `test` is `false`, we want to return `false`.

Final "Boolean Zen"

- Observation: The `if/else` is unnecessary.
 - The variable `test` stores a boolean value; its value is exactly what you want to return. So return that!

```
public static boolean bothOdd(int n1, int n2) {  
    boolean test = (n1 % 2 != 0 && n2 % 2 != 0);  
    return test;  
}
```

- An even shorter version:
 - We don't even need the variable `test`.
We can just perform the test and return its result in one step.

```
public static boolean bothOdd(int n1, int n2) {  
    return (n1 % 2 != 0 && n2 % 2 != 0);  
}
```

"Boolean Zen" template

- Replace

```
public static boolean name(parameters) {  
    if (test) {  
        return true;  
    } else {  
        return false;  
    }  
}
```

- with

```
public static boolean name(parameters) {  
    return test;  
}
```

Lab 1: Day Of the Week

Write a program that outputs the day of the week for a given date.

Create a new folder in CS50 called DayOfWeek.

Given the month, m , day, d and year y , the day of the week (Sunday = 0, Monday = 1, ..., Saturday = 6) D is given by:

$$\begin{aligned}y_0 &= y - (14 - m)/12 \\x_0 &= y_0 + y_0/4 - y_0/100 + y_0/400 \\m_0 &= m + 12 \times ((14 - m)/12) - 2 \\\mathcal{D} &= (d + x_0 + 31 \times m_0/12) \bmod 7\end{aligned}$$

Your program needs one method:

```
public static String dayOfWeek(int m, int d, int y){  
  
}
```

Day Of the Week

Write the main method so that the output is similar to the following:

Output:

Date: 9-25-2018

Day of the week: Tuesday

Use conditionals!
